

- First consider the standard case in which the F.O.C is smooth and allows to do a mean value expansion around the true value θ_0 .

$$o_p\left(\frac{1}{\sqrt{n}}\right) = \frac{\partial Q_n(\hat{\theta}_n)}{\partial \theta}$$

mean value expansion

$$o_p\left(\frac{1}{\sqrt{n}}\right) = \underbrace{\frac{\partial Q_n(\theta_0)}{\partial \theta}}_{K=1} + \underbrace{\frac{\partial^2 Q_n(\theta^*)}{\partial \theta \partial \theta'}}_{K=2} \cdot \underbrace{(\hat{\theta}_n - \theta_0)}_{K=1}$$

multiply \sqrt{n}

$$o_{p(1)} = \sqrt{n} \frac{\partial Q_n(\theta_0)}{\partial \theta} + \underbrace{\frac{\partial^2 Q_n(\theta^*)}{\partial \theta \partial \theta'}}_{K=2} \sqrt{n} (\hat{\theta}_n - \theta_0)$$

This is an interesting object since
we have θ^* and θ_n both random.
We will need a uniform LLN rather
than the usual lemma we use.

$$o_{p(1)} = \sqrt{n} \frac{\partial Q_n(\theta_0)}{\partial \theta} + \left(B(\theta_0) + o_{p(1)} \right) \sqrt{n} (\hat{\theta}_n - \theta_0)$$

Rewrite

$$\sqrt{n} (\hat{\theta}_n - \theta_0) = \left(B(\theta_0) + o_{p(1)} \right)^{-1} \sqrt{n} \frac{\partial Q_n(\theta_0)}{\partial \theta} + o_{p(1)}$$

$$\sqrt{n} (\hat{\theta}_n - \theta_0) = B(\theta_0)^{-1} \sqrt{n} \frac{\partial Q_n(\theta_0)}{\partial \theta} + o_{p(1)}$$

$\xrightarrow{*} N(0, \sigma_0)$

$$\xrightarrow{\delta} N(0, B(\theta_0)^{-1} \sigma_0 B(\theta_0)^{-1}).$$

To review how we deal with $\textcircled{*}$ recall the following assumption

$$\sup_{\theta \in \Theta_0} \left\| \frac{\partial^2 Q_n(\theta)}{\partial \theta \partial \theta'} - B(\theta) \right\| \xrightarrow{\delta} 0 \quad \text{for some non-harmonic } B(\theta) \text{ that is continuous at } \theta_0 \text{ and } B_0 := B(\theta_0) \text{ is non singular.}$$

First, notice that $\|B(\theta_n^*) - \frac{\partial^2 \Omega_n(\theta_n^*)}{\partial \theta \partial \theta'}\| = o_p(1) \times \frac{\partial^2 \Omega_n(\theta_n^*)}{\partial \theta \partial \theta'} \xrightarrow{P} B(\theta_n^*)$

proof:

$$\|B(\theta_n^*) - \frac{\partial^2 \Omega_n(\theta_n^*)}{\partial \theta \partial \theta'}\| \leq \sup_{\theta \in \Theta_0} \|B(\theta) - \frac{\partial^2 \Omega_n(\theta)}{\partial \theta \partial \theta'}\| = o_p(1)$$

$$\text{Therefore } \lim_{n \rightarrow \infty} P\left(\|B(\theta_n^*) - \frac{\partial^2 \Omega_n(\theta_n^*)}{\partial \theta \partial \theta'}\| > \varepsilon\right) \leq \lim_{n \rightarrow \infty} P(o_p(1) > \varepsilon) = 0. \quad \blacksquare$$

Secondly, notice that $\|B(\theta_0) - B(\theta_n^*)\| = o_p(1)$ provided $\theta_n^* \xrightarrow{P} \theta_0$.

proof:

$$\begin{aligned} P(\|B(\theta_0) - B(\theta_n^*)\| > \varepsilon) &= P(\|B(\theta_0) - B(\theta_n^*)\| > \varepsilon, \|\theta_n^* - \theta_0\| \leq \delta) \\ &\quad + \\ &P(\|B(\theta_0) - B(\theta_n^*)\| > \varepsilon, \|\theta_n^* - \theta_0\| > \delta) \\ &\leq P(\underbrace{\|B(\theta_0) - B(\theta_n^*)\|}_{\leq \varepsilon} > \varepsilon, \|\theta_n^* - \theta_0\| \leq \delta) \\ &\quad + \underbrace{P(\|\theta_n^* - \theta_0\| > \delta)}_{o_p(1)} \text{ by continuity of } B(\theta) \text{ at } \theta_0. \text{ We can choose such } \delta \text{ that allows this.} \\ &= 0 + o_p(1) \end{aligned}$$

Then,

$$\lim_{n \rightarrow \infty} P(\|B(\theta_0) - B(\theta_n^*)\| > \varepsilon) = \lim_{n \rightarrow \infty} o_p(1) = 0. \quad \blacksquare$$

Now, notice that our final result goes as follows

$$\begin{aligned} \frac{\partial^2 \Omega_n(\theta_n^*)}{\partial \theta \partial \theta'} &= B(\theta_n^*) + o_p(1) = B(\theta_0) + o_p(1) + o_p(1) \\ &= B(\theta_0) + o_p(1). \end{aligned}$$

- A second case arises when the F.O.C is not differentiable. We can still recover asymptotic normality under some conditions. In particular, consider the case of quantile regression:

$$op(\sqrt{n}) = \frac{\partial \text{Op}(\hat{\beta}_{\tau,n})}{\partial \beta} = \frac{1}{n} \sum_{i=1}^n (\tau - \mathbb{I}\{y_i < x_i' \hat{\beta}_{\tau,n}\}) x_i$$

Problem: non differentiable, our solution is to make it smooth using expectation for a fixed value $\hat{\beta}_{\tau,n}$.

Define

$$\begin{aligned} m(b) &= E \left[\frac{1}{n} \sum_{i=1}^n (\tau - \mathbb{I}\{y_i < x_i' b\}) x_i \right] \\ &\stackrel{\text{LIE}}{=} E[(\tau - F(x_i' b | x_i)) x_i] \quad (\text{notice that if evaluated at } \hat{\beta}_{\tau,n} \text{ this is zero, i.e. } m(\hat{\beta}_{\tau,n}) = 0) \end{aligned}$$

After adding and subtracting

$$op\left(\frac{1}{\sqrt{n}}\right) = \frac{1}{n} \sum_{i=1}^n \{ (\tau - \mathbb{I}\{y_i < x_i' \hat{\beta}_{\tau,n}\}) x_i - m(\hat{\beta}_{\tau,n}) \} + m(\hat{\beta}_{\tau,n})$$

Multiplying \sqrt{n}

$$\begin{aligned} op(1) &= \frac{1}{\sqrt{n}} \sum_{i=1}^n \{ (\tau - \mathbb{I}\{y_i < x_i' \hat{\beta}_{\tau,n}\}) x_i - m(\hat{\beta}_{\tau,n}) \} + \sqrt{n} m(\hat{\beta}_{\tau,n}) \\ &\quad \underbrace{V(\hat{\beta}_{\tau,n})}_{\text{now this is smooth!}} \quad \text{and we assume this process is SE} \\ &\quad (\sqrt{n}(\hat{\beta}_{\tau,n} - \beta_{\tau})) \end{aligned}$$

$$op(1) = V(\hat{\beta}_{\tau,n}) + op(1) + \sqrt{n} m(\hat{\beta}_{\tau,n})$$

Mean value expansion

$$op(1) = V(\hat{\beta}_{\tau,n}) + op(1) + \sqrt{n} \underbrace{m(\hat{\beta}_{\tau,n})}_{=0} + \sqrt{n} \frac{\partial m(\hat{\beta}_{\tau,n})}{\partial \beta_{\tau'}} (\hat{\beta}_{\tau,n} - \beta_{\tau'})$$

Rewrite

$$\sqrt{n} (\hat{\beta}_{\tau,n} - \beta_{\tau}) = \frac{\partial m(\hat{\beta}_{\tau,n})}{\partial \beta_{\tau'}}^{-1} V(\hat{\beta}_{\tau,n}) + op(1)$$

$$\xrightarrow{d} N(0, \frac{\partial m(\hat{\beta}_{\tau,n})}{\partial \beta_{\tau'}}^{-1} \sigma_0^2 \frac{\partial m(\hat{\beta}_{\tau,n})}{\partial \beta_{\tau'}})$$

$F(x_i' \hat{\beta}_{\tau,n} | x_i) = \tau$ we can use WLN, the function is non random, only the argument.

- A final application mentioned are two step estimators. Consider $\hat{T}_n \xrightarrow{P} T_0$ as the first step estimator. Define $m(\theta, T) = E g(w_i, \theta, T)$ and $m(\theta_0, T_0) = 0$ is the moment condition.

$$o_p\left(\frac{1}{\sqrt{n}}\right) = \frac{1}{n} \sum_{i=1}^n g(w_i, \hat{\theta}_n, \hat{T}_n)$$

mean value around θ_0

$$o_p\left(\frac{1}{\sqrt{n}}\right) = \frac{1}{n} \sum_{i=1}^n g(w_i, \theta_0, \hat{T}_n) + \frac{1}{n} \sum \underbrace{\frac{\partial g(w_i, \theta_0, \hat{T}_n)}{\partial \theta'}}_{\xrightarrow{P} \theta_0} (\hat{\theta}_n - \theta_0)$$

multiply \sqrt{n}

$$o_p(1) = \frac{1}{\sqrt{n}} \sum_{i=1}^n g(w_i, \theta_0, \hat{T}_n) + (\theta_0 + o_p(1)) \sqrt{n} (\hat{\theta}_n - \theta_0)$$

Rewrite

$$\sqrt{n} (\hat{\theta}_n - \theta_0) = -\theta_0^{-1} \frac{1}{\sqrt{n}} \sum_{i=1}^n g(w_i, \theta_0, \hat{T}_n) + o_p(1)$$

$$\pm \theta_0^{-1} \sqrt{n} E g(w_i, \theta_0, \hat{T}_n)$$

$$\sqrt{n} (\hat{\theta}_n - \theta_0) = -\theta_0^{-1} \left(\frac{1}{\sqrt{n}} \sum_{i=1}^n [g(w_i, \theta_0, \hat{T}_n) - m(\theta_0, \hat{T}_n)] \right) - \theta_0^{-1} \sqrt{n} m(\theta_0, \hat{T}_n) + o_p(1)$$

$\xrightarrow{V(\hat{T}_n)}$ and assume it's SE $V(T_0) + o_p(1)$

$$\sqrt{n} (\hat{\theta}_n - \theta_0) = -\theta_0^{-1} V(T_0) - \theta_0^{-1} \sqrt{n} m(\theta_0, \hat{T}_n) + o_p(1) \quad (\hat{T}_n - T_0)$$

Mean value exp

$$\sqrt{n} (\hat{\theta}_n - \theta_0) = -\theta_0^{-1} \left\{ \frac{1}{\sqrt{n}} \sum g(w_i, \theta_0, T_0) + \sqrt{n} m(\theta_0, T_0) + \sqrt{n} \frac{\partial m(\theta_0, T_0)}{\partial T} (\hat{T}_n - T_0) \right\}$$

$\xrightarrow{K \times 1}$ $\xrightarrow{= 0 \text{ by moment condition}}$ $\xrightarrow{P} \theta_0$ $[I_{K \times 1} : \Delta_0] N(0, V)$

$$\xrightarrow{d} -\theta_0^{-1} N(0, [I_{K \times 1} : \Delta_0] \begin{bmatrix} v_{10} & v_{20} \\ v_{20} & v_{30} \end{bmatrix} [I_{K \times 1} : \Delta_0]')$$

$$= -\theta_0^{-1} N(0, [v_{10} + \Delta_0 v_{20} & v_{20} + \Delta_0 v_{30}] \begin{bmatrix} I_K \\ \Delta_0' \end{bmatrix})$$

$$= -\theta_0^{-1} N(0, \underbrace{v_{10} + \Delta_0 v_{20} + v_{20} \Delta_0' + \Delta_0 v_{30} \Delta_0'}_{\sim \Delta_0})$$

$$= N(0, \theta_0^{-1} \Delta_0 \theta_0^{-1})$$

provided

$$\begin{bmatrix} \frac{1}{\sqrt{n}} \sum g(w_i, \theta_0, T_0) \\ \sqrt{n} (\hat{T}_n - T_0) \end{bmatrix} \xrightarrow{d} N \left(\begin{bmatrix} 0 \\ 0 \end{bmatrix}, \begin{bmatrix} v_{10} & v_{20} \\ v_{20} & v_{30} \end{bmatrix} \right).$$

What if we didn't take the SE approach?

$$O_p\left(\frac{1}{\sqrt{n}}\right) = \frac{1}{n} \sum_{i=1}^n g(w_i, \theta_n^*, T_n^*)$$

mean value expansion around θ_0

$$O_p\left(\frac{1}{\sqrt{n}}\right) = \frac{1}{n} \sum_{i=1}^n g(w_i, \theta_0, T_n^*) + \frac{1}{n} \sum \underbrace{\frac{\partial g(w_i, \theta_0^*, T_n^*)}{\partial \theta^*} \cdot (\theta_n^* - \theta_0)}_{\rightarrow \theta_0}$$

multiply \sqrt{n}

$$O_p(1) = \frac{1}{\sqrt{n}} \sum_{i=1}^n g(w_i, \theta_0, T_n^*) + (\theta_0 + O_p(1)) \sqrt{n} (\theta_n^* - \theta_0)$$

mean value expansion around T_0

$$O_p(1) = \frac{1}{\sqrt{n}} \sum_{i=1}^n g(w_i, \theta_0, T_0) + \frac{1}{\sqrt{n}} \sum_{i=1}^n \frac{\partial g(w_i, \theta_0, T_n^*)}{\partial \tau} (T_n^* - T_0) + (\theta_0 + O_p(1)) \sqrt{n} (\theta_n^* - \theta_0)$$

Rewrite

$$\sqrt{n} (\theta_n^* - \theta_0) = -\theta_0^{-1} \left\{ \frac{1}{\sqrt{n}} \sum_{i=1}^n g(w_i, \theta_0, T_0) + \frac{1}{n} \sum_{i=1}^n \frac{\partial g(w_i, \theta_0, T_n^*)}{\partial \tau} \sqrt{n} (T_n^* - T_0) \right\} + O_p(1)$$

$\rightarrow \theta_0$ under different conditions!

and we still get the same asymptotic distribution.

where $\Delta_0 = \frac{\partial E_g(w_i, \theta_0, T_0)}{\partial \tau}$. To get this result now we

require

$$\frac{1}{n} \sum_{i=1}^n \frac{\partial g(w_i, \theta_0, T_n^*)}{\partial \tau} = \Delta_0 + O_p(1).$$

This can be achieved by assuming, for example,

\star I believe Vadim has some Lemmas with sufficient conditions for this: $\sup_{T \in T} \left\| \frac{1}{n} \sum_{i=1}^n \frac{\partial g(w_i, \theta_0, T)}{\partial \tau} - \frac{\partial E_g(w_i, \theta_0, T)}{\partial \tau} \right\| = O_p(1)$

Then

$$\frac{1}{n} \sum_{i=1}^n \frac{\partial g(w_i, \theta_0, T_n^*)}{\partial \tau} = \Delta(T_n^*) + O_p(1) = \Delta(T_0) + O_p(1)$$

provided $T_n^* \xrightarrow{P} T_0$ and $\Delta(T_0)$ is continuous at T_0 .

- Efficient GLVs as a special case + Bracketing :

$$E(Y_i - X_i' \beta_0 | Z_i) = 0$$

$u_i = m(Y_i, X_i, \beta_0)$

④ Notice that GLS is the case of $Z_i = X_i$.

$$g^*(u) = \frac{E(X_i | u)}{E(u_i^2 | Z_i)}$$

and suppose we have a consistent estimator

$$\hat{g}_n(u_i) \xrightarrow{P} g^*(u_i)$$

$$(Z'X)^{-1} Z' Y$$

which is our first step estimator.

$$\sqrt{n}(\hat{\beta}_n - \beta_0) = \left(\frac{1}{n} \sum_{i=1}^n \hat{g}_n(u_i) X_i' \right)^{-1} \frac{1}{\sqrt{n}} \sum_{i=1}^n \hat{g}_n(u_i) u_i$$

$\xrightarrow{P} (E g^*(u) X_i')$

$$= (E g^*(u) X_i')^{-1} \frac{1}{\sqrt{n}} \sum_{i=1}^n \hat{g}_n(u_i) u_i + o_p(1)$$

$$(E g^*(u) X_i') \xrightarrow{\pm} \sqrt{n} E \hat{g}(u) u_i$$

$E[u_i | Z_i] = 0$
 $E g(z_i) u_i = 0$ for any measurable
 $g(\cdot)$

$$= (E g^*(u) X_i')^{-1} \left\{ \frac{1}{\sqrt{n}} \sum (g_n^*(u_i) u_i - E \hat{g}(u_i) u_i) + \sqrt{n} E \hat{g}(u) u_i \right\} + o_p(1)$$

⑤ (\hat{g}_n) and assume it's se ⑥ (g^*) + $o_p(1)$

$$= (E g^*(u) X_i')^{-1} \left\{ \frac{1}{\sqrt{n}} \sum (g_n^*(u_i) u_i - E g^*(u_i) u_i) + \sqrt{n} E \hat{g}(u) u_i \right\} + o_p(1)$$

= 0 by moment condition, recall
 that $\hat{g}_n(\cdot)$ is some measurable
 function.

$$= (E g^*(u) X_i')^{-1} \left\{ \frac{1}{\sqrt{n}} \sum g^*(u_i) u_i \right\} + o_p(1)$$

$$\xrightarrow{D} (E g^*(u) X_i')^{-1} N(0, E u_i^2 g^*(u) g^*(u)')$$

Recall now that \mathcal{G}_n is a functional, so the definition we use is

$$\limsup_{n \rightarrow \infty} P \left(\sup_{g \in \mathcal{G}} \sup_{|g_1 - g_2| \leq \delta} |\mathcal{G}_n(g_1 - g_2)| > \epsilon \right) < \epsilon$$

$\hookrightarrow L_2 \text{ norm}$

Given two functions ℓ, u of W_i such that $\ell(W_i) \leq u(W_i)$. we can define a bracket $[\ell, u] := \{g \in \mathcal{G}: \ell \leq g \leq u\}$. An ϵ -bracket satisfies $\|u - \ell\|_2 \leq \epsilon$. $u(W_i), \ell(W_i)$

We say a collection of brackets $\{[\ell, u]\}_{\ell, u}: \ell \in A\}$ covers \mathcal{G} if $\mathcal{G} \subset \bigcup_{\ell \in A} [\ell, u]$.

the bracketing number $N_{[]}(\epsilon, \mathcal{G}, L_p)$ is the smallest number of ϵ -brackets $[\ell, u]$

needed to cover \mathcal{G} .

④ Roughly $\epsilon \rightarrow \infty \Rightarrow N_{[]} \rightarrow 1$

$\epsilon \rightarrow 0 \Rightarrow N_{[]} \rightarrow \infty$ or some large number.

The entropy with respect to bracketing is $\log N_{\mathcal{C}}(\epsilon, g, \mathcal{L}_P)$, which measures the size/complexity of the family of functions \mathcal{G} .

Allow me to rewrite

$$\limsup_{n \rightarrow \infty} P \left(\sup_{g \in \mathcal{G}} \sup_{\substack{g_1, g_2 : \|g_1 - g_2\| < \delta \\ g \in \mathcal{G}}} |G_n(g_1 - g_2)| > \epsilon \right) < \epsilon$$

$\hookrightarrow L_2 \text{ norm}$ $\underbrace{\|g\|}_{\leq \delta}$

$$\limsup_{n \rightarrow \infty} P \left(\sup_{\substack{g : \|g\| < \delta, \\ g \in \mathcal{G}}} |G_n(g)| > \epsilon \right) < \epsilon$$

Use Markov Ineq

$$\limsup_{n \rightarrow \infty} P \left(\sup_{\substack{g : \|g\| < \delta, \\ g \in \mathcal{G}}} |G_n(g)| > \epsilon \right) \leq \limsup_{n \rightarrow \infty} \left\{ E \sup_{\substack{g : \|g\| < \delta, \\ g \in \mathcal{G}}} |G_n(g)| \cdot \frac{1}{\epsilon} \right\}$$

OK... that doesn't seem helpful, but there's a proposition we could use.

Proposition.- Suppose that (i) $\|g\|_2 \leq \delta$ for all $g \in \mathcal{G}$

(ii) There's an envelope function \bar{G} such that $|g| \leq \bar{G}$ for all $g \in \mathcal{G}$.
Then, for some constant $C > 0$,

$$E \sup_{g \in \mathcal{G}} |G_n(g)| \leq C \cdot \left\{ \int_0^\delta \sqrt{\log N_{\mathcal{C}}(\epsilon, g, L_2)} d\epsilon + \sqrt{n} E[\bar{G}] \cdot \left(\bar{G} > \delta \sqrt{\frac{n}{\log N_{\mathcal{C}}(\delta, g, L_2)}} \right) \right\}$$

Using this proposition gives

- 1) $\lim_{n \rightarrow \infty}$
2) we choose δ , we can set $f \rightarrow 0$.

$$\limsup_{n \rightarrow \infty} P \left(\sup_{\substack{g : \|g\| < \delta, \\ g \in \mathcal{G}}} |G_n(g)| > \epsilon \right) \leq \lim_{n \rightarrow \infty} \frac{C}{\epsilon} \left\{ \underbrace{\int_0^\delta \sqrt{\log N_{\mathcal{C}}(\epsilon, g, L_2)} d\epsilon}_{\textcircled{A}} + \underbrace{\sqrt{n} E[\bar{G}] \cdot \left(\bar{G} > \delta \sqrt{\frac{n}{\log N_{\mathcal{C}}(\delta, g, L_2)}} \right)}_{\textcircled{B}} \right\}$$

\textcircled{A} $\lim_{n \rightarrow \infty} \lim_{\delta \rightarrow 0} \int_0^\delta \sqrt{\log N_{\mathcal{C}}(\epsilon, g, L_2)} d\epsilon = 0$ using dominated convergence theorem.

We require a dominating function, like $K \sqrt{\log N_{\mathcal{C}}(\epsilon, g, L_2)}$ for some $K > 1$. Then we also need that it's integrable

$$\int_0^\infty K \sqrt{\log N_{\mathcal{C}}(\epsilon, g, L_2)} d\epsilon = O(1), \text{ so a sufficient condition is}$$

$$\int_0^\infty \sqrt{\log N_{\mathcal{C}}(\epsilon, g, L_2)} d\epsilon = O(1).$$

$$\textcircled{B} \quad \lim_{n \rightarrow \infty} \lim_{\delta \rightarrow 0} \sqrt{n} E \left[\bar{G} \mathbb{1} \left(\bar{G} > \sqrt{n} \frac{\delta}{\sqrt{\log N(\delta, g, L)}} \right) \right]$$

This says that $\frac{\bar{G}}{\sqrt{n} \alpha(\delta)} > 1$, so if we multiply it we increase this number.

$$\leq \lim_{n \rightarrow \infty} \lim_{\delta \rightarrow 0} \sqrt{n} E \left[\bar{G} \frac{\bar{G}}{\sqrt{n}} \cdot \frac{1}{\alpha(\delta)} \mathbb{1} (\bar{G} > \sqrt{n} \alpha(\delta)) \right]$$

goes outside, it's non random

$$= \lim_{n \rightarrow \infty} \lim_{\delta \rightarrow 0} \frac{1}{\alpha(\delta)} E \left[\bar{G}^2 \mathbb{1} (\bar{G} > \sqrt{n} \alpha(\delta)) \right] \stackrel{=} 1$$

we want this to enter inside

By the dominated convergence theorem with \bar{G}^2 as dominating function and given that $E \bar{G}^2 < \infty$, which can be shown if we choose, for instance, $\bar{G} = |Z| + |W|$.

$$= \lim_{\delta \rightarrow 0} \frac{1}{\alpha(\delta)} E \left[\bar{G}^2 \lim_{n \rightarrow \infty} \mathbb{1} (\bar{G} > \sqrt{n} \alpha(\delta)) \right] = 0.$$

$\stackrel{=} 0$

Putting it all together implies

$$\limsup_{n \rightarrow \infty} P \left(\sup_{\substack{g: \|g\|_1 \leq \delta, \\ g \neq 0}} |\bar{G}(g)| > \varepsilon \right) \leq \lim_{n \rightarrow \infty} C \cdot \left\{ \underbrace{\int_0^\delta \sqrt{\log N(\varepsilon, g, L)} d\delta}_{\textcircled{A}} + \underbrace{\sqrt{n} E \left[\bar{G} \mathbb{1} \left(\bar{G} > \delta \sqrt{\frac{n}{\log N(\delta, g, L)}} \right) \right]}_{\textcircled{B}} \right\}$$

give sufficient conditions for this to go to 0.

$\approx 0 \quad \therefore \blacksquare$
